

# Rice Type Classification using CNN

## Project Description:

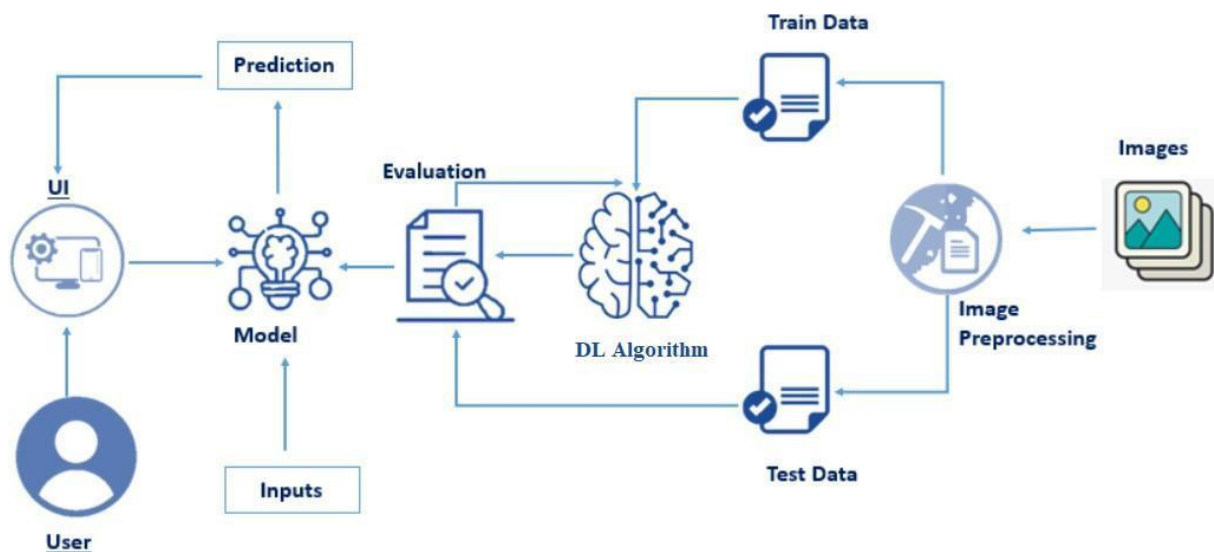

Rice comes in various types, each requiring different amounts of water, manure, and care for optimal growth. Identifying the type of rice is crucial, but constantly consulting agricultural experts can be costly for farmers. To address this challenge, we have developed an AI model that helps farmers determine the type of rice with ease and accuracy.

Our solution enables users to simply upload an image of a rice grain and click the submit button. The AI model will then predict the probable type of rice based on the image, capable of identifying up to five different types. This tool is beneficial for farmers, agricultural scientists, home gardeners, and anyone involved in rice cultivation.

The AI model is built using Convolutional Neural Networks (CNNs) with transfer learning, a technique known for its superior performance in image analysis and classification tasks. Specifically, we employed the MobileNetv4 architecture, a popular choice for transfer learning in image analysis due to its high effectiveness and efficiency.

With this model, we aim to empower farmers and agriculture enthusiasts with a cost-effective, reliable, and easy-to-use tool for rice type identification.

## Technical Architecture:

## **Project Objectives:**

By the end of this project, you'll understand:

- Preprocessing of images and augmentation of images.
- Applying Transfer learning algorithms on the dataset.
- How deep neural networks detect the disease.
- You will be able to know how to find the accuracy of the model.
- You will be able to Build web applications using the Flask framework.

## **Project Flow:**

- The user interacts with the UI (User Interface) to choose the image.
- The chosen image analyzed by the model which is integrated with flask application.
- The MobileNet Model analyzes the image, then the prediction is showcased on the Flask UI.

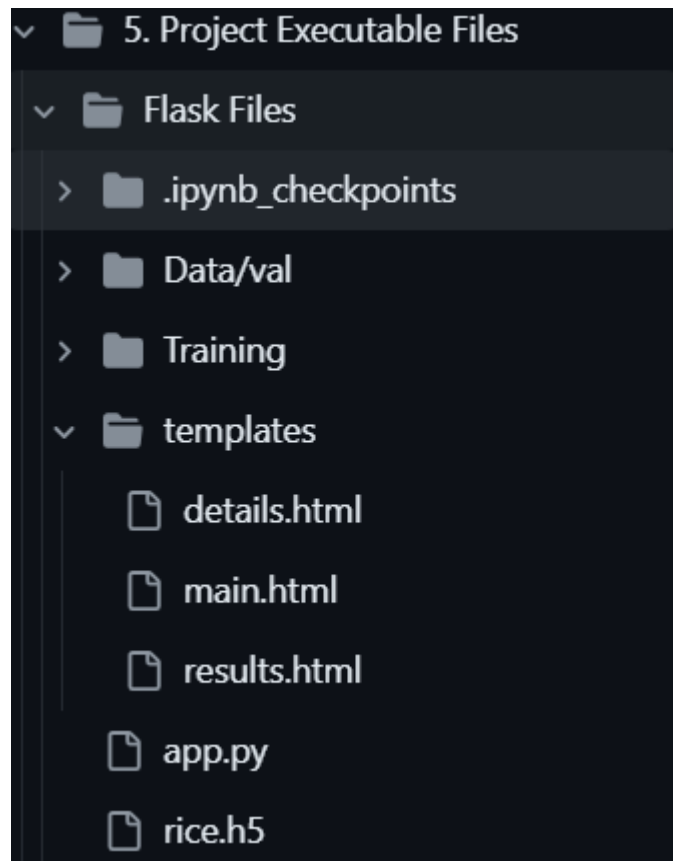

To accomplish this, we must complete all the activities and tasks listed below

- Data Collection.
  - Create a Train and Test path.
- Data Pre-processing.
  - Import the required library
  - Configure ImageDataGenerator class
  - Apply ImageDataGenerator functionality to Trainset and Test set
- Model Building
  - Pre-trained CNN model as a Feature Extractor
  - Adding Dense Layer
  - Configure the Learning Process
  - Train the model
  - Save the Model
  - Test the model
- Application Building

- Create an HTML file
- Build Python Code

## Project Structure:

Create a Project folder which contains files as shown below

- Static folder contains css files
- Template folder contains all 3 HTML pages.
- Data folder contains Training and Validation images
- Training file consist of rice\_classification\_v2.ipynb , rice.h5 model

## Milestone 1: Data Collection

There are many popular open sources for collecting the data. Eg: kaggle.com, UCI repository, etc.

### Activity 1: Download the dataset

Collect images of Tomato Leaves. Images are then organized into subdirectories based on their respective names as shown in the project structure.

In this project, we have collected images of 10 types of Tomato Leaf images like Heatly, Spider Mites, Yellow leaf curl, etc. and they are saved in the respective sub directories with their respective names.

You can download the dataset used in this project using the below link

Dataset: <https://www.kaggle.com/datasets/muratkokludataset/rice-image-dataset>

#### **Note: For better accuracy train on more images**

We are going to build our training model on Kaggle as they provide accelerators like GPUs and TPUs.

#### **Note: The Google Drive notebook will also be provided in the GitHub link mentioned at the end of the project**

A new Kaggle Notebook should be created under the dataset link provided.

This notebook will directly link to the Kaggle Dataset.

```
d2 = r"D:\\Programming\\Project\\Rice-Type-Classification-Using-CNN\\Rice_Image_Dataset"
data_dir = r"D:\\Programming\\Project\\Rice-Type-Classification-Using-CNN\\Rice_Image_Dataset" # Datasets path
data_dir = pathlib.Path(data_dir)
data_dir
```

```
WindowsPath('D:/Programming/Project/Rice-Type-Classification-Using-CNN/Rice_Image_Dataset')
```

### Activity 2: Splitting Data on Classes

Inside the data folder there are several folders for different classes.

Name	Status	Date modified	Type
 Arborio		11-07-2024 16:01	File folder
 Basmati		11-07-2024 16:08	File folder
 Ipsala		11-07-2024 16:10	File folder
 Jasmine		11-07-2024 16:12	File folder
 Karacadag		11-07-2024 16:14	File folder

[3]:

```
arborio = list(data_dir.glob('Arborio/*'))[:600]
basmati = list(data_dir.glob('Basmati/*'))[:600]
ipsala = list(data_dir.glob('Ipsala/*'))[:600]
jasmine = list(data_dir.glob('Jasmine/*'))[:600]
karacadag = list(data_dir.glob('Karacadag/*'))[:600]
```

## Milestone 2: Image Preprocessing

In this milestone we will be improving the image data that suppresses unwilling distortions or enhances some image features important for further processing, although perform some geometric transformations of images like rotation, scaling, translation, etc.

### Activity 1: Importing the libraries

Import the necessary libraries as shown in the image

.

```

import tensorflow as tf
from tensorflow import keras
import tensorflow_hub as hub
from sklearn.model_selection import train_test_split
import matplotlib.pyplot as plt
import matplotlib.image as img
import PIL.Image as Image
import cv2
import os
import numpy as np
import pandas as pd
import pathlib

```

## Activity 2: Changing size of the images:

Since the input dimensions of the MobileNet are (224,224,3). We have to resize our images in the same way.

```

img = cv2.imread(str(df_images['arborio'][0])) # Converting it into numerical array
img.shape # Its currently 250 by 250 by 3

```

```
(250, 250, 3)
```

Currently the size of images is (250,250,3).

```

resized_img = cv2.resize(img, (224, 224))

```

## Activity 3: Link images to different classes

Here we have 5 classes and the images need to be labelled with appropriate classes.

```

# Contains the images path
df_images = {
    'arborio' : arborio,
    'basmati' : basmati,
    'ipsala' : ipsala,
    'jasmine' : jasmine,
    'karacadag': karacadag
}

# Contains numerical labels for the categories
df_labels = {
    'arborio' : 0,
    'basmati' : 1,
    'ipsala' : 2,
    'jasmine' : 3,
    'karacadag': 4
}

X, y = [], [] # X = images, y = labels
for label, images in df_images.items():
    for image in images:
        img = cv2.imread(str(image))
        resized_img = cv2.resize(img, (224, 224))
        X.append(resized_img)
        y.append(df_labels[label])

```

## Activity 4: Splitting Data in Train set, Validation and Test set

We will split the data in training, validation and testing sets.

```

# Standarizing
X = np.array(X)
X = X/255
y = np.array(y)

```

```

# Separating data into training, test and validation sets
X_train, X_test_val, y_train, y_test_val = train_test_split(X, y)
X_test, X_val, y_test, y_val = train_test_split(X_test_val, y_test_val)

```

## Activity 5: Preview of images

```
[4]: fig, ax = plt.subplots(ncols=5, figsize=(20,5))
fig.suptitle('Rice Category')
arborio_image = img.imread(arborio[0])
basmati_image = img.imread(basmati[0])
ipsala_image = img.imread(ipsala[0])
jasmine_image = img.imread(jasmine[0])
karacadag_image = img.imread(karacadag[0])

ax[0].set_title('arborio')
ax[1].set_title('basmati')
ax[2].set_title('ipsala')
ax[3].set_title('jasmine')
ax[4].set_title('karacadag')

ax[0].imshow(arborio_image)
ax[1].imshow(basmati_image)
ax[2].imshow(ipsala_image)
ax[3].imshow(jasmine_image)
ax[4].imshow(karacadag_image)
```

[4]: <matplotlib.image.AxesImage at 0x7f55e1c0d6d0>

Here we can see that there are 5 different classes, we can see their names above the images. We can see that each disease can be seen directly from the image.

## Milestone 3: Model Building

Now it's time to build our model. Let's use the pre-trained model which is MobileNetv4, one of the convolution neural net (CNN) architecture which is considered as a very good model for Image classification.

### Activity 1: Pre-trained CNN model as a Feature Extractor

For one of the models, we will use it as a simple feature extractor by freezing all the convolution blocks to make sure their weights don't get updated after each epoch as we train our own model.

Here, we have considered images of dimension (224, 224, 3).

Also, we have assigned trainable = False because we are using convolution layer for features extraction and wants to train fully connected layer for our images classification.

```
[10]: mobile_net = 'https://tfhub.dev/google/tf2-preview/mobilenet_v2/feature_vector/4' # MobileNetv4 link
mobile_net = hub.KerasLayer(
    mobile_net, input_shape=(224,224, 3), trainable=False) # Removing the last layer
```

### Activity 2: Adding Dense Layer

A dense layer is a deeply connected neural network layer. It is the most common and frequently used layer.

Let us create a model object named model with inputs as mobile\_net and output as dense layer.

```
[11]: num_label = 5 # number of labels

model = keras.Sequential([
    mobile_net,
    keras.layers.Dense(num_label)
])
```

The number of neurons in the Dense layer is the same as the number of classes in the training set. The neurons in the last Dense layer, use softmax activation to convert their outputs into respective probabilities.

Understanding the model is a very important phase to properly use it for training and prediction purposes. Keras provides a simple method, summary to get the full information

about the model and its layers.

```
model.summary()
```

Model: "sequential"

Layer (type)	Output Shape	Param #
keras_layer (KerasLayer)	(None, 1280)	2257984
dense (Dense)	(None, 5)	6405
Total params: 2,264,389		
Trainable params: 6,405		
Non-trainable params: 2,257,984		

### Activity 3: Configure the Learning Process

The compilation is the final step in creating a model. Once the compilation is done, we can move on to the training phase. The loss function is used to find errors or deviations in the learning process. Keras requires a loss function during the model compilation process.

Optimization is an important process that optimizes the input weights by comparing the prediction and the loss function. Here we are using adam optimizer

Metrics are used to evaluate the performance of your model. It is similar to the loss function, but not used in the training process

```
model.compile(  
    optimizer="adam",  
    loss=tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True),  
    metrics=['acc'])
```

### Activity 4: Train the model

Now, let us train our model with our image dataset. The model is trained for 10 epochs and after every epoch, the current model state is saved if the model has the least loss encountered till that time. We can see that the training loss decreases in almost every epoch.

**fit** functions used to train a deep learning neural network

### Arguments:

- Epochs: an integer and number of epochs we want to train our model for.
- validation\_data can be either:
  - an inputs and targets list
  - a generator
  - an inputs, targets, and sample\_weights list which can be used to evaluate the loss and metrics for any model after any epoch has ended

```
[14]: history = model.fit(X_train, y_train, epochs=10, validation_data=(X_val, y_val))

Epoch 1/10
71/71 [=====] - 13s 47ms/step - loss: 0.5700 - acc: 0.8333 - val_loss: 0.2491 - val_acc: 0.9362
Epoch 2/10
71/71 [=====] - 2s 32ms/step - loss: 0.1594 - acc: 0.9680 - val_loss: 0.1619 - val_acc: 0.9574
Epoch 3/10
71/71 [=====] - 2s 31ms/step - loss: 0.1114 - acc: 0.9769 - val_loss: 0.1280 - val_acc: 0.9521
Epoch 4/10
71/71 [=====] - 2s 31ms/step - loss: 0.0853 - acc: 0.9813 - val_loss: 0.1157 - val_acc: 0.9628
Epoch 5/10
71/71 [=====] - 2s 31ms/step - loss: 0.0719 - acc: 0.9840 - val_loss: 0.0968 - val_acc: 0.9681
Epoch 6/10
71/71 [=====] - 2s 31ms/step - loss: 0.0589 - acc: 0.9862 - val_loss: 0.0903 - val_acc: 0.9681
Epoch 7/10
71/71 [=====] - 3s 36ms/step - loss: 0.0518 - acc: 0.9889 - val_loss: 0.0817 - val_acc: 0.9734
Epoch 8/10
71/71 [=====] - 2s 31ms/step - loss: 0.0452 - acc: 0.9911 - val_loss: 0.0774 - val_acc: 0.9734
Epoch 9/10
71/71 [=====] - 2s 31ms/step - loss: 0.0411 - acc: 0.9889 - val_loss: 0.0750 - val_acc: 0.9734
Epoch 10/10
71/71 [=====] - 2s 31ms/step - loss: 0.0377 - acc: 0.9916 - val_loss: 0.0754 - val_acc: 0.9681
```

## Activity 5: Testing the Model

Model testing is the process of evaluating the performance of a deep learning model on a dataset that it has not seen before. It is a crucial step in the development of any machine learning model, as it helps to determine how well the model can generalize to new data.

```
model.evaluate(X_test,y_test)
```

18/18 ————— 3s 182ms/step - acc: 0.9925 - loss: 0.0529  
[0.06141575053334236, 0.9893238544464111]

```
from sklearn.metrics import classification_report

y_pred = model.predict(X_test, batch_size=64, verbose=1)
y_pred_bool = np.argmax(y_pred, axis=1)

print(classification_report(y_test, y_pred_bool))
```

9/9 ————— 3s 339ms/step

	precision	recall	f1-score	support
0	0.98	1.00	0.99	108
1	0.98	0.98	0.98	112
2	1.00	0.99	1.00	121
3	0.98	0.99	0.99	110
4	1.00	0.98	0.99	111
accuracy			0.99	562
macro avg	0.99	0.99	0.99	562
weighted avg	0.99	0.99	0.99	562

## Activity 6: Visualizing Accuracy and Loss

The accuracy and loss can be visualized to check the correlation between the epochs and loss or epochs and accuracy.

```
from plotly.offline import iplot, init_notebook_mode
import plotly.express as px
import pandas as pd

init_notebook_mode(connected=True)

acc = pd.DataFrame({'train': history.history['acc'], 'val': history.history['val_acc']})

fig = px.line(acc, x=acc.index, y=acc.columns[0:], title='Training and Evaluation Accuracy every Epoch', markers=True)
fig.show()
```

Training and Evaluation Accuracy every Epoch

```
loss = pd.DataFrame({'train': history.history['loss'], 'val': history.history['val_loss']})

fig = px.line(loss, x=loss.index, y=loss.columns[0:], title='Training and Evaluation Loss every Epoch', ma
fig.show()
```

Training and Evaluation Loss every Epoch

## Activity 7: Testing the Model:

Here we will take a image of basmati rice and check what our model predicts for the same.

```
a1 = cv2.imread(r"D:\\Programming\\Project\\Rice-Type-Classification-Using-CNN\\Rice_Image_Dataset\\Jasmine\\Jasmine (10).jpg')
a1 = cv2.resize(a1,(224,224))
a1 = np.array(a1)
a1 = a1/255
a1 = np.expand_dims(a1, 0)
pred = model.predict(a1)
pred = pred.argmax()
pred
```

1/1 — 0s 117ms/step  
3

```
for i, j in df_labels.items():
    if pred == j:
        print(i)
```

jasmine

As we can see our model has predicted the rice to be Basmati rice, means our model is giving correct predictions.

## Milestone 4: Save the Model

The model is saved as rice.h5

A .h5 file is a data file saved in the hdf5 format. It contains multidimensional arrays of scientific data.

```
model.save("rice.h5")
```

## Milestone 5: Application Building

In this section, we will be building a web application that is integrated to the model we built. A UI is provided for the user where they have to upload the image for predictions. The entered image is given to the saved model and prediction is showcased on the UI.

This section has the following tasks

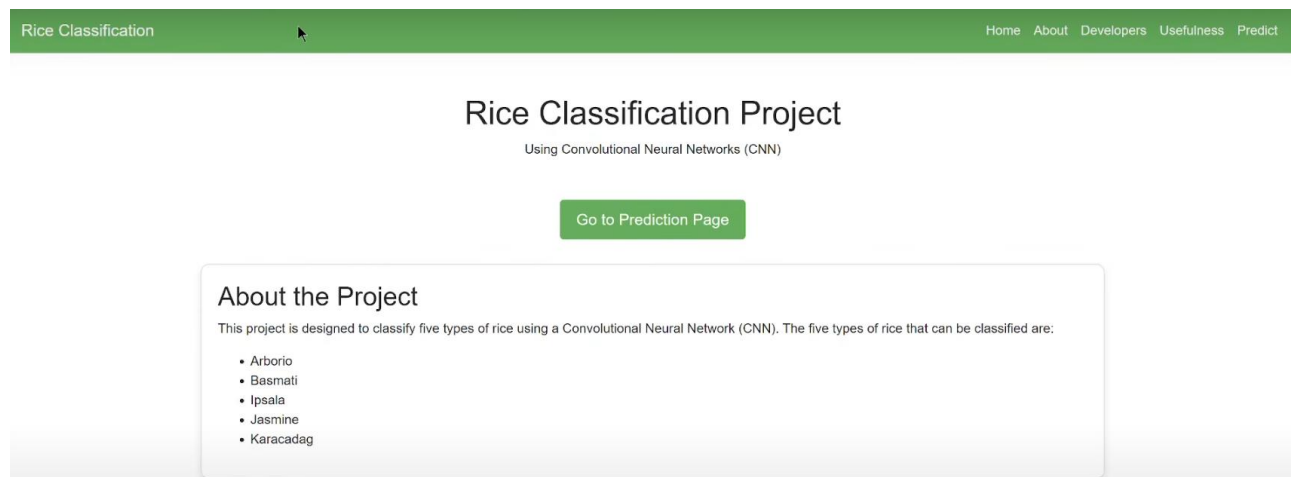

- Building HTML Pages

### Activity1: Building Html Pages:

For this project create 3 HTML files namely

- Index.html
- Details.html
- Results.html

Let's see how our index.html page looks like:

## Developers

This project was created by a team of four developers:

- *Tanish Maheshwari*
- *Aryan Aggarwal*
- *Jaswanth M*
- *Kathirgamam Venkatesan*

Our Team ID is SWTID1720109344

## Project Usefulness

The Rice Classification Project is highly useful in various sectors:

- **Agriculture:** Helps farmers and agricultural experts in identifying and categorizing different types of rice, ensuring the right type is grown and harvested.
- **Food Industry:** Assists in quality control and sorting processes in rice milling and packaging plants, leading to better product differentiation and market segmentation.
- **Research:** Provides a tool for researchers to analyze rice samples, leading to advancements in agricultural research and development.
- **Consumer Awareness:** Educates consumers about different types of rice, helping them make informed choices about their food purchases.

When you click on the Go to Prediction button, it will display the below page. You can test the model by passing a image

[Home](#) / [Details](#)

## Details Page

### Upload Your Image

Choose Image:  No file chosen

## Activity 2: Build Python code:

Import the libraries

```
import tensorflow as tf
import tensorflow_hub as hub
import warnings
warnings.filterwarnings('ignore')
import h5py
import numpy as np
import os
from flask import Flask, request, render_template
from tensorflow import keras
import cv2
import tensorflow_hub as hub
```

Loading the saved model and initializing the flask app

```
model = keras.models.load_model(filepath='rice.h5', custom_objects={'KerasLayer': hub.KerasLayer})
app = Flask(__name__)
```

Render HTML pages:

```
@app.route('/')
def home():
    return render_template('main.html')

@app.route('/details')
def pred():
    return render_template('details.html')
```

Once we uploaded the file into the app, then verifying the file uploaded properly or not. Here we will be using declared constructor to route to the HTML page which we have created earlier.

In the above example, '/' URL is bound with index.html function. Hence, when the home page of the web server is opened in browser, the html page will be rendered. Whenever you enter the values from the html page the values can be retrieved using POST Method.

```

@app.route('/result', methods=['GET', 'POST'])
def predict():
    if request.method == "POST":
        f = request.files['image']
        basepath = os.path.dirname(__file__)
        filepath = os.path.join(basepath, 'Data', 'val', f.filename)
        f.save(filepath)

        a2 = cv2.imread(filepath)
        a2 = cv2.resize(a2, (224, 224))
        a2 = np.array(a2)
        a2 = a2 / 255
        a2 = np.expand_dims(a2, 0)

        pred = model.predict(a2)
        pred = pred.argmax()

        df_labels = {
            'arborio': 0,
            'basmati': 1,
            'ipsala': 2,
            'jasmine': 3,
            'karacadag': 4
        }
        for i, j in df_labels.items():
            if pred == j:
                prediction = i

        return render_template('results.html', prediction_text=prediction)

```

Here we are routing our app to predict function. This function retrieves all the values from the HTML page using Post request. That is stored in variable image and then converted into an array. This array is passed to the model.predict() function. This function returns the prediction. And this prediction value will rendered to the text that we have mentioned in the result.html page earlier.

### Main Function:

```

if __name__ == "__main__":
    app.run(debug=True, use_reloader=False)

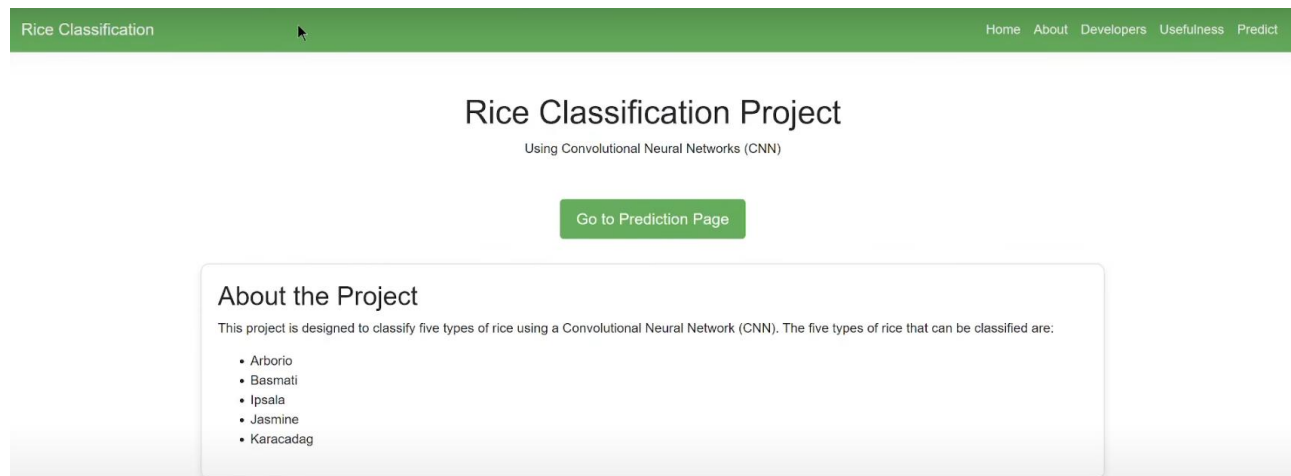

```

### Activity 3: Run the application

- Open the Anaconda prompt from the start menu.
- Navigate to the folder where your Python script is.
- Now type the “python app.py” command.
- Navigate to the localhost where you can view your web page.
- Click on the predict button from the top right corner, enter the inputs, click on the submit button, and see the result/prediction on the web.

```
WARNING: This is a development server.
